a new report has revealed that a massive eruption of the Indonesian volcano Toba could have killed every person on Earth around 70,000 years ago. Toba's global-scale eruption around 74,000 years ago resulted in the Toba Lake, a huge volcanic lake which covered an area of 14,000 square miles of coastal East Africa. The aim of this project was to test the capacity of the new platform for automatic detection and prediction of pyroclastic flows, their dynamics and development in space and time. Usually the automatic monitoring of pyroclastic flows, for the purpose of early warning, is limited to the detection and tracking of the plume using radar, satellite or seismic data. The objective here was to enhance the detection of this hazard and to study its dynamics in space and time using remotely-sensed data from the WorldView-2 and Sentinel-2 satellites. The analysis of the environmental

---

conditions at the beginning of the eruptions, such as the thermal conditions and the atmospheric pressure, will be of paramount importance for the development of several forecasting methods. to this end, the list of volcanoes and volcanoes that displayed an eruptive crisis, starting from april 2001, is reported on extended data tables 7, 8, 9 and 10. data are from pyrovolc volcano monitor and nasa/jpl-caltech's ges disc server. a pyroclastic flow is a kind of volcanic explosion, in which a mixture of hot gas, rock fragments, volcanic bombs, and tephra erupts in a cohesive, dense, quickly moving, self-destructing, and destructive mass. the density of the material required to form a pyroclastic flow can vary. for example, ash is a very fluid material that may be able to hold or even re-suspend itself; clasts of denser material like pumice will tend to sink to the bottom of the flow, while ash and scoria can remain near the top. a viscous clast-rich pyroclastic flow is the result of a large volume of volcanic material that moves slowly and over a large area. such a flow is able to move a long distance without too much disruption.

## Volcano Tool V2 2 8

mace carries survival gear from individual items to complete kits. the company also focuses on selling self-contained, fully functional, lightweight equipment that is designed to ensure that a user will have everything they need to successfully complete their chosen adventure. in this tutorial, we will use the volcano plot to show how distances can be converted to z-values (p-values, in this case). first we will use the volcano\_genes file from the original paper. the volcano\_genes file contains gene names, which i am unable to keep in a csv file that matches the volcano\_genes file by default. however, any field names can be translated to gene names. we will convert this to a csv file using pandoc. this will be the volcano\_genes\_to\_csv. in the followings steps, i will use the volcano\_genes as an example dataset. examine the volcano\_genes\_to\_googleform\_legend file. it contains gene names. there will be one row for each volcano. each row will contain two columns, representing volcano and the volcano-genes's labels. explore the volcano\_genes\_to\_csv file. it contains a volcano volcano\_name genes\_desc . separators are

---

tabs ( ). each row represents a volcano. these can be gene names and/or volcano coords. if you would like volcano names in the volcano\_genes\_to\_csv file, you can directly copy the volcano\_genes\_to\_csv file (as it is) to the code editor. data = np.array([[ 'volcano's label/volcano name', 'genes/', 'volcano's coords x,y,z', 'volcano's colors ', 'volcano's labels', 'label', 'color' ]]) plt.volcano(data, palette='gist\_rainbow') plot for volcano 1 the next volcano plot will be generated from the data in volcano\_genes\_to\_csv. we first use the np.array function to create a 3-dimensional array, data. 5ec8ef588b
